

JARVIS-LIKE ASSISTANT PROJECT ROADMAP

This document outlines a step-by-step roadmap to build a personal assistant capable of controlling your laptop using natural language commands.

Phase 1: Command to Action System

Goal: Build a reliable system that executes commands like opening apps, searching the web, and playing songs.

Core components include input handling, intent detection using keywords, and action execution.

Example: 'Play Kesariya' opens YouTube search.

Phase 2: Flexible Language Handling

Goal: Allow variations in commands. The system understands different ways of saying the same thing.

Example: 'Play Kesariya', 'Can you play Kesariya?', 'I want to hear Kesariya'.

This phase improves usability without using AI yet.

Phase 3: AI Integration

Goal: Use an AI model to understand intent from complex sentences.

Example: 'I feel bored, play something nice' is interpreted as playing relaxing music.

This requires API integration and structured output handling.

Phase 4: Action Engine

Goal: Enable multi-step workflows.

Example: 'Start coding session' opens VS Code, browser, and project files.

This involves chaining multiple actions together.

Phase 5: Memory and Personalization

Goal: Make the assistant remember user preferences.

Example: 'Play my gym playlist' triggers a predefined playlist.

Requires storing user data locally.

Phase 6: Semi-Autonomous Assistant

Goal: Assistant can decide actions based on intent.

Example: 'Prepare me to work' triggers a full setup automatically.

Includes decision-making logic and safety constraints.

Final Notes

Start simple. Build Phase 1 and Phase 2 first. Gradually add intelligence and automation.

Focus on usefulness, not complexity.
